***Abstract*—GDP forecasting is a crucial component to policy-making and business planning. In order to do so, we must be able to bring in many complex, non-linear factors such as tourism, military spending, import/export, birth rate into the equation in order to make these forecasts. We will be training and predicting using 2 different models to predict the GDP of the USA, England, and Japan for 1 year in the future. We will compare the two for which has better accuracy. One of the models is Facebook's Prophet which is a Bayesian-based regression model for univariate time series forecasting. Our goal is to get within 85% accuracy for our predictions.**

## I. Introduction

GDP is a way that governments measure the health and development of their country. We will be trying to create models that will forecast a country's GDP in the future.

## II. Literature Review

The gaps is that it is difficult sometimes to be able to feed in outliers to the model accurately.

## III. Methodology

We will be using datasets from accredited sources like the World Bank.

## IV. Results

Hopefully the results will be interesting.

## V. Discussion

The results show that we can never be 100% accurate, but can try and be as close as possible.

## VI. Conclusion

Machine Learning is a great way to forecast future GDP or sales.
